

Fuel solar container module principle diagram

Overview

The container-type power generation fuel cell system comprises: a container with doors formed on one or both sides; a plurality of stack modules which is provided in the container, and in which fuel cell stacks are stacked and connected, and the fuel cell. Hydrogen and oxygen to produce water and electricity. A fuel cell consists of three main components: an anode, a cathode, and an electrolyte. The anode is where the fuel (usually hydrogen) is fed into the cell, while the cathode is where the oxygen reacts with water external to the battery. A fuel cell is an electrochemical device that generates electrical energy from fuel via an electrochemical reaction. The process is reverse of water electrolysis in which electric current breaks down water into hydrogen and oxygen ions. In fuel cells, hydrogen (fuel) and oxidizer (oxygen or air). Fuel Cell Working Principle explains that it is an electrochemical device that converts chemical energy of a conventional fuel directly into low voltage D.C. electrical energy. It is then described as a primary battery in which fuel and oxidizer are stored external to the battery and fed to it when. The present invention relates to a container-type power generation fuel cell system, which is capable of integrated management of multiple stack modules. The container-type power generation fuel cell system comprises: a container with doors formed on one or both sides; a plurality of stack modules. In this page we describe, briefly, the architecture of our Fuel Cells Systems, you can refer to the page Hydrogen Fuel Cells Technology, for general information about fuel cell systems, while you can refer to the page Fuel Cell Electrochemical Reaction, for more details about the theoretical.
