This study investigates the thermal performance of a single-slope solar still integrated with paraffin wax as a phase change material (PCM) under varying water depths (15 L, 20 L, and 25 L). This study investigates the thermal performance of a single-slope solar still integrated with paraffin wax as a phase change material (PCM) under varying water depths (15 L, 20 L, and 25 L). The experimental arrangement with a galvanized iron basin equipped with insulated walls and just an inclined. The utilization of solar desalination processes using solar stills to maintain the purity of water. The purpose of this process is to remove impurities and salt from water to make it suitable for consumption. The study involves analyzing various factors that influence the conditions of the solar. Photovoltaic (PV) systems have emerged as a leading solution for sustainable energy generation. However, the performance of PV modules deteriorates with increased operating temperatures. This study investigates the enhancement of PV performance through the integration of phase change material. Temperature density with small temperature fluctuate. caused by low/unavailable solar irradiation. Current research on acid and palmitic acid-based LHTES unit. In this regard, shellac with different Phase Change Materials (PCMs). This combination leads to increased product of the medium during the phase change. Paraffin wax is selected as the phase change material (PCM) which act as LHTES. The water condensate on the inner glass is removed with a time interval of 30 minutes with minimum possible velocity. For each modifications hourly output, instantaneous efficiency are recorded and compared with. This paper is focused on the charging and discharge analysis of Paraffin wax (melting temperature of 58-60°C) which is used as phase change material in thermal energy storage system. To analyse the performance of Paraffin wax, a simple and economical experimental setup has been constructed that.
